

Distribution Box Main Line Connection Diagram

Article Overview

A distribution box receives the main power supply through a main isolator or MCB, passes it through an RCCB for protection, and then distributes it to individual MCBs for subcircuits.

Main Line Connection

The main power supply from the utility or energy meter enters the distribution box via phase (live) and neutral wires. These wires are first connected to a main isolator or double-pole MCB, which acts as the primary switch to control the entire electrical system and allows manual disconnection for maintenance or emergencies. From the main isolator, the phase wire is routed to an RCCB (Residual Current Circuit Breaker), which protects against leakage currents, electric shocks, and insulation faults. The neutral wire is connected to a neutral link, which distributes neutral to all subcircuits.

Distribution to Subcircuits

After the RCCB, the phase wire is connected in parallel to multiple MCBs (Miniature Circuit Breakers). Each MCB protects an individual subcircuit, such as lighting, fans, or air conditioners, from overcurrent due to overload or short circuits. Single-pole MCBs are typically used for standard loads, while double-pole MCBs may be used for special or high-power loads. The neutral wires from each subcircuit are connected to the neutral link, and the earth wires from the supply and loads are connected to the earth terminal to ensure proper grounding
