

# Fiber optic pigtails are susceptible to interference

## Overview

Fiber optic cable is the network cable type least susceptible to signal interference. Because it transmits data as pulses of light through glass threads rather than electrical signals through copper, it is completely immune to electromagnetic interference (EMI). How cables connect to the entire system dictates the success of the network. The optical signals that pass through the link can only do so triumphantly with minimal interference, low attenuation. Fiber pigtails are simple in appearance, yet essential in function. Get the wrong connector type, the wrong polish, or skip proper fusion splicing technique—and you're looking at elevated signal loss, increased back reflection, and a. When you build or upgrade a fiber network, the same four words pop up everywhere— fiber optic (bare fiber), pigtail, patch cord, optical cable. Mixing them up drives costs higher, increases loss, and slows your rollout. Every fiber optic cable installer or a company that deals in optical installation needs to know the reasons behind. Fiber optic pigtails have only one terminated connector on one side but bare fibers on another side.
