

How to distribute light modules in a one-to-many configuration for lights

Article Overview

To distribute multiple light modules from a single source, use parallel wiring, splitters, or networked control systems to ensure even power distribution and synchronized operation.

Electrical Distribution

For LED strips or low-voltage lights, the most reliable method is parallel wiring. Each light module connects directly to the power source rather than chaining in series. This prevents voltage drop, which can cause lights farther from the source to appear dimmer. Ensure the total current draw does not exceed 80% of the power supply's rated capacity to maintain safety and longevity of the system . Using LED splitters is another effective approach. A splitter divides the power from a single source into multiple outputs, allowing each module to receive adequate voltage and current. This simplifies wiring and increases flexibility for complex layouts . For traditional AC lighting circuits, pigtail in junction boxes is commonly used. Incoming power is spliced to multiple wires, each feeding a separate fixture. This method ensures all lights receive consistent power and allows for safe, code-compliant installation .

Control Considerations

If you want synchronized control of multiple lights, especially for RGB or addressable LEDs, consider networked control systems like DMX or PoE lighting. DMX controllers send digital signals to each module, allowing precise timing, color changes, and eff...
