

The output from the optical splitter is an interface

Article Overview

The output from an optical splitter can be considered an optical interface, as it delivers distributed optical signals to network endpoints such as ONTs.

Understanding Optical Splitter Outputs

An optical splitter is a passive device that divides a single input optical signal into multiple output signals without requiring power. Each output is transmitted through a separate fiber, which connects directly to end-user devices like Optical Network Terminals (ONTs) in a Fiber-to-the-Home (FTTH) network. In this sense, each output fiber functions as an interface, providing a physical and optical connection point for network devices.

Characteristics of the Output

- **Split Ratio:** Defines how the input signal is divided among outputs (e.g., 1x4, 1x32, 1x64). Higher split ratios distribute the signal to more endpoints but reduce the optical power per output.
- **Uniformity:** Ensures that each output receives a consistent portion of the input signal, which is critical for reliable network performance.
- **Insertion Loss:** The natural attenuation of the signal due to splitting, which must be accounted for when designing the network.
